

VM Selection for Financial Exchanges in the Cloud

Daniel Duclos-Cavalcanti (Student), Muhammad Haseeb (NYU Supervisor), Navidreza Asadi (TUM Supervisor) Chair of Communication Networks, School of CIT Technical University of Munich (TUM)

1 Overview

Financial exchanges consider a migration to the cloud for scalability, robustness, and cost-efficiency. Jasper [1] presents a scalable and fair multicast solution for cloud-based exchanges, addressing the lack of cloud-native mechanisms for such. To achieve this, Jasper employs an overlay multicast tree, leveraging clock synchronization, kernel-bypass techniques, and more. However, there are opportunities for enhancement by confronting the issue of inconsistent VM performance within identical instances. LemonDrop [2] tackles this problem, detecting under-performing VMs in a cluster and selecting a subset of VMs optimized for a given application's latency needs. Yet, we believe that LemonDrop's approach of using time-expensive all-to-all latency measurements and an optimization routine for the framed Quadratic Assignment Problem (QAP) is overly complex. The proposed work aims to develop a simpler and scalable heuristic, that achieves reasonably good results within Jasper's time constraints. We expect to encounter challenges in being able to reach considerable improvements under such tight latency windows.

2 Objectives

Develop a VM selection heuristic for Financial Exchanges in the cloud.

- 1. Implement a Server-Client Manager application:
 - (a) Server: Allows user to run, terminate and report on processes across a cluster.
 - i. Connects to client nodes (VMs) and issues action-requests:
 - A. Action(A): Launch a process/program, store and report PID.
 - B. Action(B): Report information on ongoing process.
 - C. Action(C): Kill a previously ran process.
 - (b) Client: Waits on Server's connection and requests.
- 2. Develop Testbench Framework via Server-Client Manager:
 - (a) Server allocates N VMs, then runs and terminates Jasper on initial configuration.
 - (b) Server applies **Heuristic** to produce new tree configuration.
 - (c) Server re-deploys Jasper on new configuration.
- 3. Heuristic: Choose K VMs, apply selection method for F nodes, assign them to next layer.
 - (a) K VMs Selection: Initially random, we intend on expanding.
 - (b) ${f F}$ VMs Selection: Analyzing reports on intra-VM OWD latency among the ${f K}$ nodes.

3 Experimental Setup

Cloud VM instances of c2d-highcpu-8 type would be deployed on Google Cloud's Platform. Each machine offers 8 virtual AMD Milan CPU's, 16GB of Memory and 16Gbps of Network Bandwidth. Results would be compared among a vanilla Jasper run, a heuristic-proposed and a LemonDrop proposed configuration of Jasper. Experiments would be run across two pre-selected tree structures, chosen based on a realistic cloud exchange scenario and Jasper's best fitting configurations for them.
